

Evaluating bi-orthogonality of Rayleigh-Lamb eigenmodes in elastic plates

Terry Schuh

Mentors: Karwan Rostem
and Edward Wollack

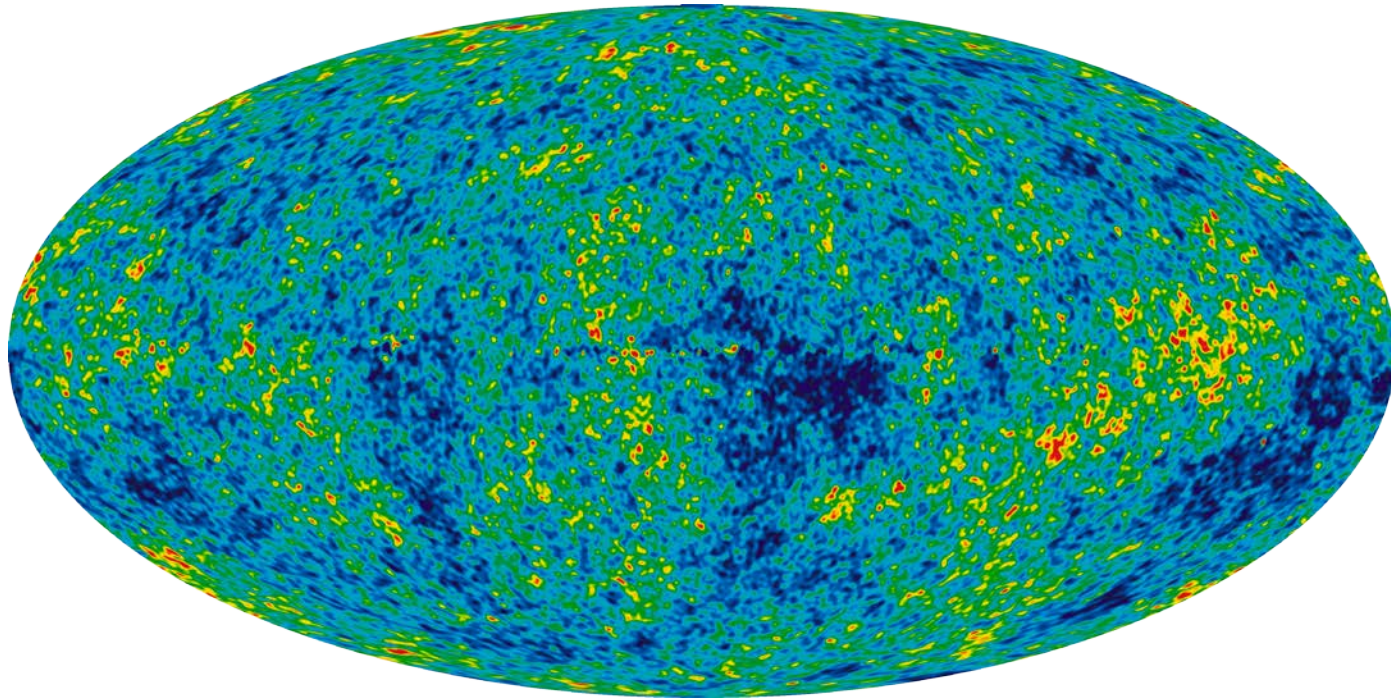

Motivation

- Astrophysics requires more and more precise measurements
- This requires extremely sensitive detectors
- To reach desired sensitivities, detectors need to be very cold and, components need to be very small in size

Very Cold

$$T_{\text{detector}} \ll T_{\text{source}}$$

$$T_{\text{CMB}} \sim 3 \text{ K}$$
$$T_{\text{detectors}} \sim 0.1 \text{ K}$$

Very Small

E-M Spectrum

← Increasing
Frequency (ν)

| | | | | | | |
|---------------|--------|----|---------|----|------------|-------|
| γ rays | x rays | UV | visible | IR | Microwaves | Radio |
|---------------|--------|----|---------|----|------------|-------|

Increasing
Wavelength (λ) →

observational cosmology lab

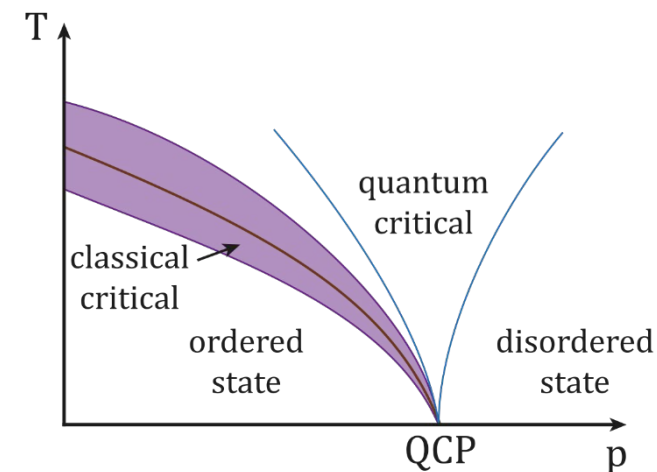

λ ranges from
0.1 – 10 mm

Scale of detector physical features are $\sim 0.5 - 1000 \mu\text{m}$

Mesoscopic Limit

- At these temperatures and physical scales, device operation approaches the mesoscopic limit
- Temperatures < 1 K
- Electromagnetic wavelengths set the ~ 1 mm pixel scale
- Thermal radiation wavelengths set scales of detector dimensions
- Classical system \rightarrow quantum system
- Continuum limit \rightarrow discrete modes

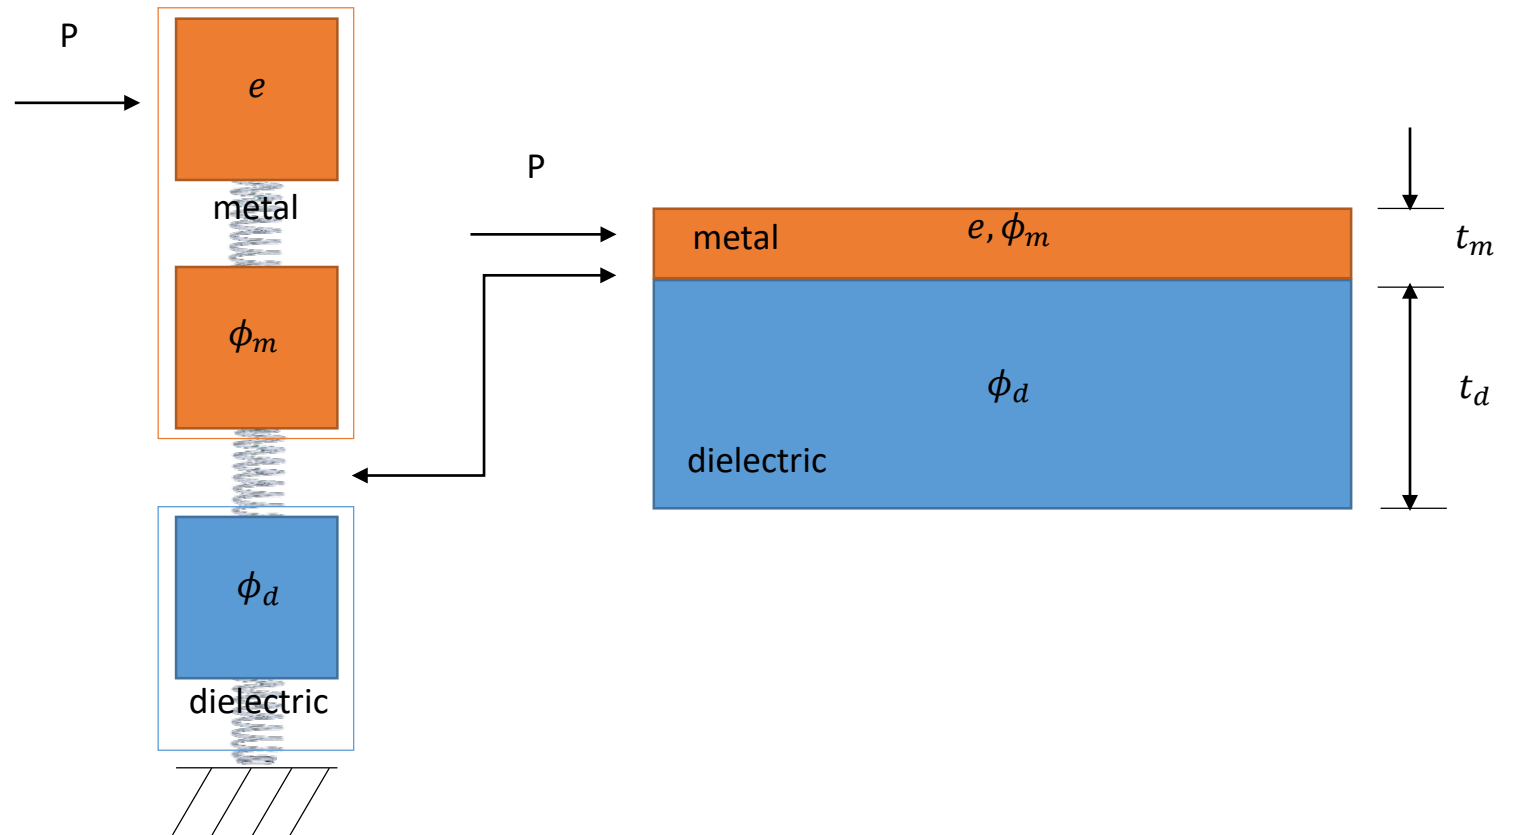

Our Goal

- Metals and dielectrics are integral to radiation detectors
- Electron-phonon (e - ϕ) interaction is key to detector response
- Need to understand this interaction to make detectors work
- That's what I worked on!

How To Do It

- At the mesoscopic limit, phonons treated as elastic waves in a solid
- Thus we evaluate the phonon modes and use “bi-orthogonality” to understand coupling

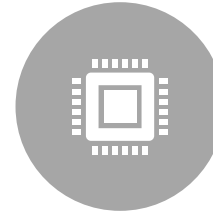

Conclusions and Future Work

- Wanted to improve sensitivity of current astrophysical detectors
- Important to understand e - ϕ and ϕ - ϕ coupling at low temperatures and in nano-scale structures
- Successfully evaluated bi-orthogonality relation between elastic eigenmodes in uniform/single layer silicon plate
- Model more complicated, multi-layered plate using COMSOL
- Evaluate bi-orthogonality relation for eigenmodes in complete model

What I Did

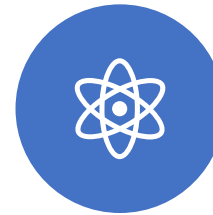

Worked with
bi-orthogonality

Used COMSOL and
MATLAB everyday

Developed and
solved a simplified
version of plate

Learned a ton more
physics

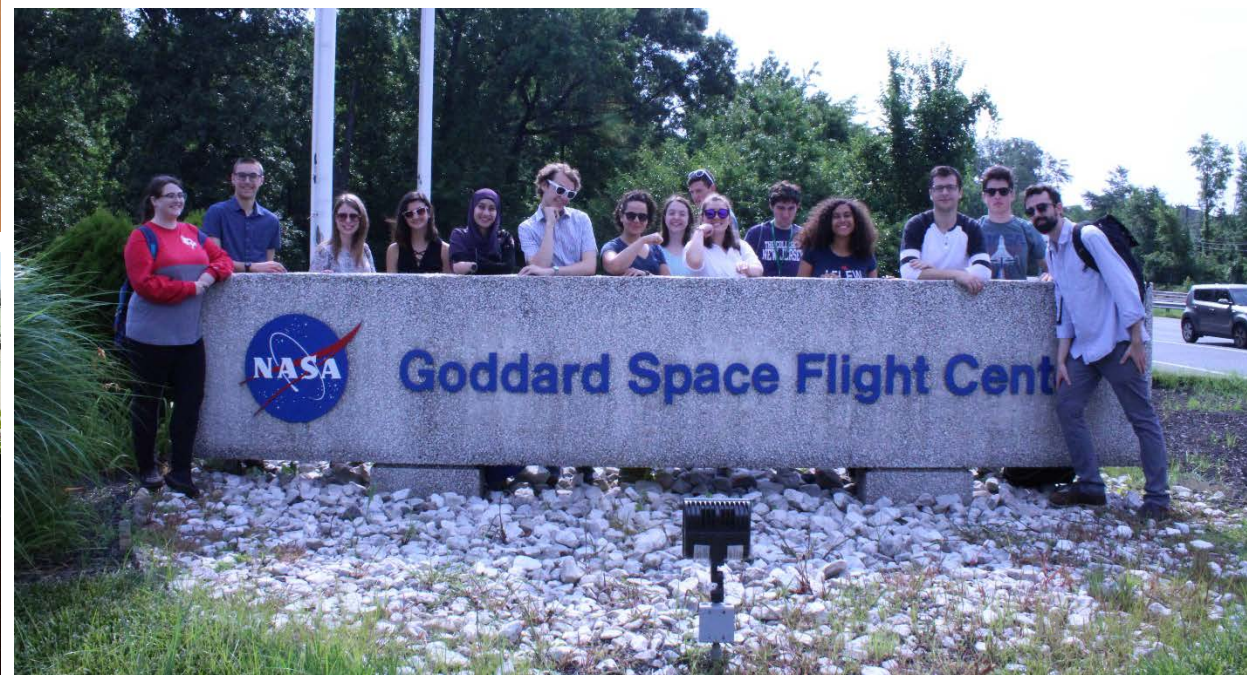

Improved coding
abilities

Developed more
research skills

Bi-orthogonality

- A set of functions $\{f_1(n, x), f_2(n, x)\}$ are bi-orthogonal if:

$$\int f_1(m, x) f_1(n, x) dx = C_1 \delta_{mn}$$

$$\int f_2(m, x) f_2(n, x) dx = C_2 \delta_{mn}$$

$$\int f_1(m, x) f_2(n, x) dx = 0$$

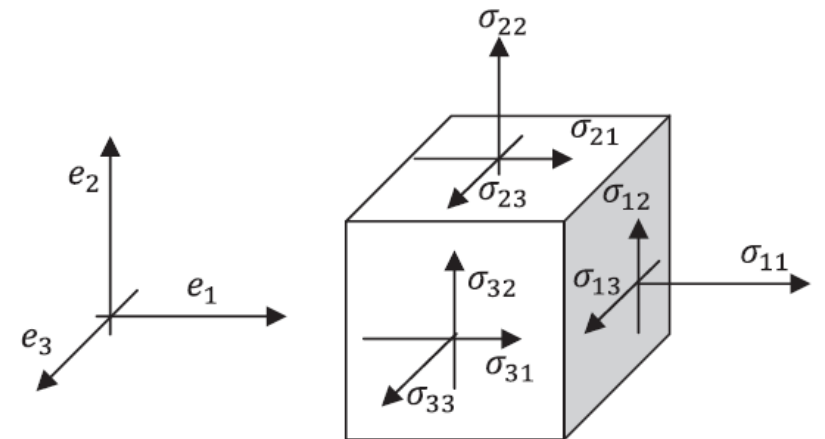

where $m \neq n$ and C_1 and C_2 are real constants.

Bi-orthogonality

- In our specific case the bi-orthogonality relation is as follows:

$$\int \left(\sigma_{xz}^{*(1)} u_z^{(2)} - \sigma_{xx}^{(2)} u_x^{*(1)} \right) dz = 0$$

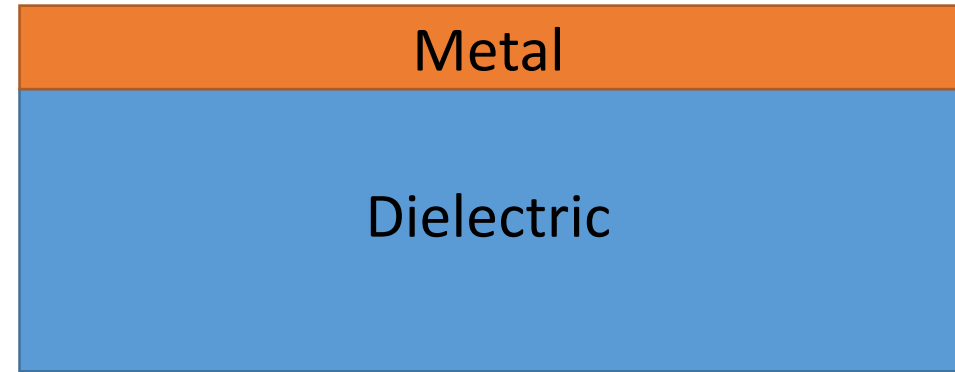

- σ and u are the stress and displacement in the plate
- superscripts represent eigenmodes
- subscripts refer to specific vector components
- asterisks signify complex conjugates
